Improving maternal health remains a significant challenge in Bangladesh. Lack of awareness and socio-cultural and religious taboos, among other factors, contribute to the current maternal mortality rate of 194 per 100,000 live births in Bangladesh [1]. One evidence-based intervention [2, 3] to increase awareness of the causes of maternal mortality and to encourage advocacy that will improve maternal health outcomes is social mobilization through community support groups (CSGs). As part of the demand side of a larger maternal and neonatal health (MNH) intervention, icddr,b formed CSGs by involving community members in Shahjadpur sub-district. The objectives of the CSGs are: to identify pregnant women and sensitize pregnant women and members of her family about the importance of using skilled maternal care; to provide support to the poor and disadvantaged through fund raising and arranging transport to a facility for mothers with complications; and to establish links between the community and the facility.

**Approach:**

By October 2010, 64 CSGs had been formed. Each CSG was comprised of 30 committee members serving in one of three different capacities - an advisory committee, executive committee and volunteer committee. The aim of the committee members was to persuade pregnant mothers and their family members to communicate with local health facilities and health service providers (family welfare assistants, family welfare visitors, health assistants, family planning inspectors, and most importantly the community-based skilled birth attendants (CSBAs)), to ensure the availability of maternal health care services when required. The effectiveness of CSGs was assessed using a baseline and a follow-up structured questionnaire survey during November’08 to March’09 and October’10 to November’10 among mothers who delivered six months prior to the interview date.

**Results:**

In the baseline and follow-up surveys, 3,158 and 2,725 mothers were recruited respectively for interview. Following the baseline survey, at least 640 courtyard-sessions of CSGs were conducted by female volunteers covering 6,500 mothers. During the baseline survey nearly three-fourths of the mothers (70%) reported receiving any antenatal care (ANC); which increased to 84% after formation of CSGs and covering almost all the unions of Shahjadpur sub-district. Skilled attendance at delivery was 26% at baseline and increased to 42% at the follow-up survey. Mothers who attended the courtyard-sessions conducted by CSGs during the time period received substantially more ANC and skilled delivery care than the mothers who did not attend (Figures 1 and 2).
Conclusion:
The intervention findings suggest that the courtyard-sessions using CSGs made noticeable contribution to improving maternal health-seeking behaviour in terms of ANC visits and skilled attendance at delivery.

Implications:
Participatory approaches through courtyard-sessions and family involvement in care stimulated by the CSGs appear effective in improving maternal health-seeking behaviour in Bangladesh. There was some operational cost (US$ 225 in 2010) to form each CSG and provide hand-outs for training to the volunteer committee. However, involvement of elite groups of villagers in the CSGs may increase the likelihood that the program will be sustainable in the long run.

Recommendations:
- Formation of CSGs over the entire sub-district to increase community awareness regarding appropriate maternal health actions;
- Encourage CSGs to be self-sustainable and to take independent initiatives to address a range of maternal and neonatal health issues;
- Birth preparedness initiatives should first empower household members through CSGs; and
- To further address the gap between knowledge and action, CSGs should also focus on arrangement of transport and blood donors, to help limit potential delays in referral to facility.
